

```
// first, initialize CUDA environment
```

```
Initialize CUDA and allocate memory for input image and accumulator array.
```

```
// then, define a kernel function outside of the main function
```

```
Define a kernel function:
```

```
    Calculate x, y coords of the pixel this thread is responsible for
```

```
    blockIdx * blockDim + threadIdx
```

```
    For each pixel (x, y) in the image:
```

```
        If the pixel is an edge (Image[x, y] > 0):
```

```
            For each theta in range of angles:
```

```
                Calculate  $\rho = x * \cos(\theta) + y * \sin(\theta)$ 
```

```
                Increment the accumulator at (theta, rho)
```

```
// Launch and call the kernel
```

```
Set grid and block dimensions
```

```
Call the kernel:
```

```
    houghTransform<<gridDimensions, blockDimensions>>(d_img, d_accumulator, width, height, max_rho, num_thetas)
```

```
Synchronize CUDA device to make sure all threads are done
```

```
// Copy results back to host and free space
```

```
Copy accumulator from Device to Host
```

```
Free device memory
```

```
Process the accumulator in MATLAB (call this C function in MATLAB)
```
